

The Use of Alexa

I. Objective

For my EPRP project, I was tasked with helping VOLI create an Alexa skill to let patients know if the medication they were taking interacted with alcohol, and possibly, to what degree. To solve this problem, I needed to find an accurate and reliable database of drug interactions, and host an interpreting backend on a web server that Alexa could access for responses.

II. Background

A comprehensive database of drug interactions needed to be identified in order for Alexa to predict interaction results. Doctors usually use private, subscription based engines to “search... for articles on alcohol medication interactions, diseases worsened by alcohol use, alcohol metabolism, absorption and distribution,” and interpret results from sources such as MEDLINE [3]. There is no nice way for Alexa to do this, but the National Institute of Health provides an API that searches the DrugBank, a database similar to MEDLINE that stores drug information, side effects, and interactions, for public access [1].

III. Research Approach

A. Task One — Identifying medications that interact with alcohol

The first task was to find a reliable database that could easily be queried for alcohol in its list of interaction entries and that had a public API. Inputting ‘ethanol’ into the NIH Interactions API¹, an API that returns json data of drugs that interact with an input, a comprehensive list of drug interactions with alcohol was able to be extracted (see Table 1). This list was checked by Dr. Alison Moore and found to be too comprehensive,

¹ <https://rxnav.nlm.nih.gov/InteractionAPIs.html#>

meaning it did not exclude drugs with more moderate interaction effects. For example, caffeine was listed, and although it does tamper with alcohol's effect, the results are not severe and rarely problematic. Thus, the drugs given by the NIH database were categorized as “moderately interactive.”

Since the NIH database was not exclusionary, a list of more severe reactants needed to be compiled. The NIAAA² was used for this since the drugs listed were known to cause problematic interactions with alcohol. The NIAAA did not have a nice API to use, but since it contained only a few entries, they were permanently stored as a string variable in the backend (see Figure 1).

After a suitable database was identified, the return data needed to be processed for Alexa to access and give a response. The backend was created to make REST requests to the NIH and process the return into a nice, searchable Python list. Then, both lists were searched for the drug Alexa interpreted from the patient, and the backend would return one of the following responses: {'This medication severely interacts with alcohol': True} if the drug was found in the NIAAA string variable, {'This medication moderately interacts with alcohol': True} if the drug was found from the NIH data, or {'I could not find this medication in our database. Ask your doctor before drinking while taking this medication': True} if the drug could not be located in either location.

B. Task Two — Understanding Drug Names

² <https://www.niaaa.nih.gov/publications/brochures-and-fact-sheets/harmful-interactions-mixing-alcohol-with-medicines>

Before the backend could be called to determine if the medication interacted with alcohol, Alexa would first have to interpret the drug name the patient was saying. This was done using the NIH's spellingCheck API which returns a json list of possible spelling variations for an incorrectly spelt input drug name. Alexa would repeat the drug back to the patient for confirmation. If Alexa was incorrect, spellingCheck API was called to compile a list of possible suggestions and these were iteratively read aloud to the patient until the right spelling was identified.

Finally, VoiceFlow was used to create a conversation flow from the moment Alexa understood that the patient was asking if their drug interacted with alcohol and ending with a response from Alexa or with a request from the patient to exit (see Figure 2). Alexa would access this VoiceFlow conversation from a REST API I had setup on the lab's cloud computer using a lambda request.

IV. Moving Forward

It would be useful to allow for the possibility of patients to say their drug name again instead of bombarding them with a list of spelling suggestions. If Alexa could not spot the difference between the first and second utterance of the medication name, it would continue reading off the spelling suggestions list. Also, more research needs to go into starting up the program and developing possible use cases patients might ask.

V. Resources/Databases used

1. Wishart DS, Knox C, Guo AC, Shrivastava S, Hassanali M, Stothard P,

Chang Z, Woolsey J. DrugBank: a comprehensive resource for in silicon drug discovery and exploration. Nucleic Acids Res. 2006 Jan 1;34(Database issue):D668-72. 16381955
